

# Periprocedural code status discussions for inpatients undergoing percutaneous gastrostomy tube placement

Rebecca Kalman, MD and Rebecca Hutchinson, MD MPH

Maine Medical Center, Palliative Medicine, 66 Bramhall Street, Portland, ME 04102

## Background

- Gastrostomy tube (G-tube) placement is a common procedure offered in patients with life limiting diseases.
- Given the nature of the underlying disease process, these patients may present for G-tube with a “Do-Not-Resuscitate” (DNR) order in place.
- Both the American Society of Anesthesiologists and the American College of Surgeons have published statements that encourage discussion of periprocedural risks in the setting of patient’s values and preferences with an emphasis on communication, preservation of patient self-determination, and shared decision-making.
- Policies that automatically suspend or uphold DNR orders are generally discouraged.
- Despite this, there is inconsistency and confusion amongst medical professionals and patients regarding what happens to limitations on code status in the context of a procedure.
- This can be even more ambiguous for “minor” procedures or procedures that occur outside of the operating room such as G-tube placement.
- The goal of this study is to examine whether or not code status conversations are documented for inpatients undergoing G-tube placement and to explore the factors associated with the presence or absence of a documented conversation.

## Methods

- Retrospective chart review was performed on all adult inpatients (n=254) undergoing G-tube placement at Maine Medical Center from May, 2016 through May, 2017.
- Primary outcome was presence of documented code status discussions for patients with code status other than “Full” at the time of their G-tube placement.
- Secondary outcomes were factors associated with having documentation of a code status discussion as well as mortality associated with inpatient G-tube placement.
- Patients < 18 years old were excluded.
- Demographics, admission diagnosis, and severity of illness score were abstracted via the electronic medical record (EMR) system at Maine Medical Center.
- Comorbid diagnoses, code status, characteristics of G-tube, and service characteristics were abstracted using a manual chart review.
- For patients with a code status other than “Full” at time of G-tube, progress and procedure related notes five days pre- and post-procedure were reviewed to determine if there was a documentation of code status discussion.
- If there was a conversation, the service who documented the discussion was noted.
- Mortality data was obtained from a combination of chart review and an internet search for obituary information.
- Data were analyzed using SAS v9.1 software

## Results

Table 1. Characteristics of Patients (N=254)

| Characteristic                      | Number | Percent |
|-------------------------------------|--------|---------|
| <b>Age</b>                          |        |         |
| < 35                                | 17     | 7       |
| 36-50                               | 36     | 14      |
| 51-65                               | 90     | 35      |
| 66-75                               | 60     | 24      |
| 76-87                               | 51     | 20      |
| <b>Sex</b>                          |        |         |
| Male                                | 157    | 62      |
| Female                              | 97     | 38      |

Figure 2. Team Documenting Conversation (n=9)

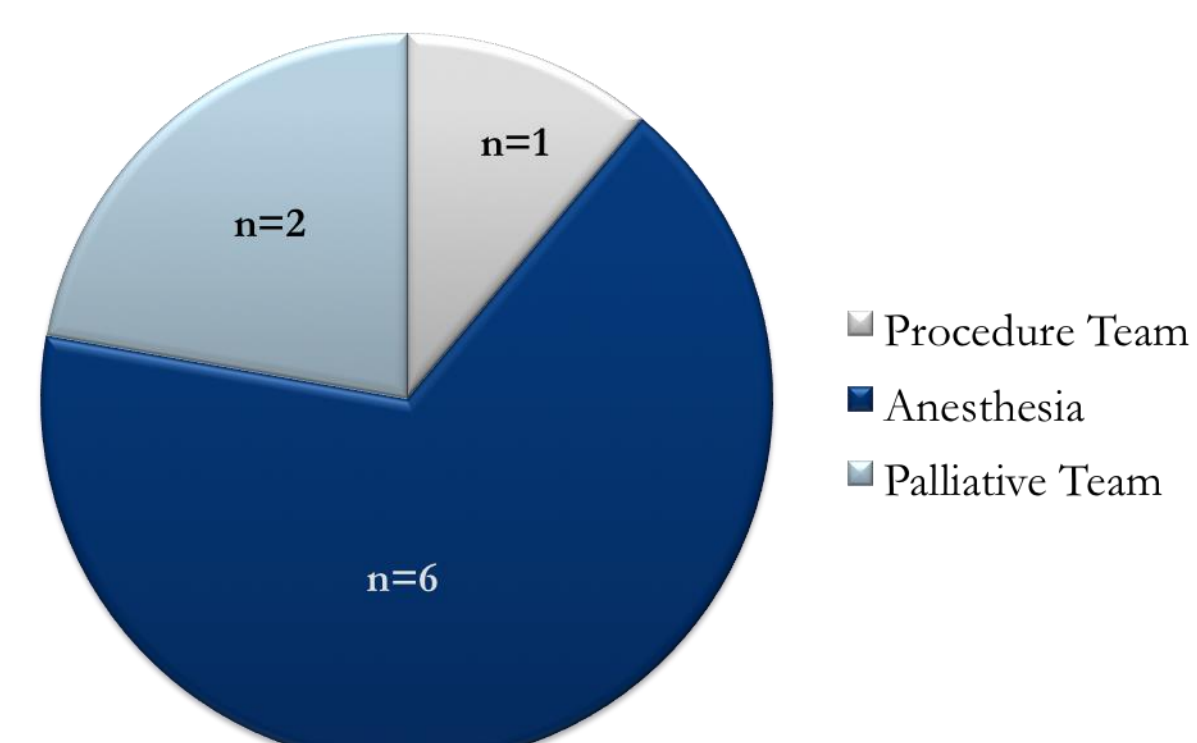

Figure 1. Mortality of inpatients who underwent G-tube placement

## Conclusions

- Of 254 adult inpatients who underwent G-tube placement from May 2016 through May 2017, 33 (13%) had code status other than “Full”.
- Of those 33 patients, only 9 (27%) had code status discussion documented regarding the procedure.
  - Documentation was performed by:
    - 11% by the procedure team
    - 67% by the anesthesia team
    - 22% by the palliative medicine team
  - No conversations were documented by the primary team
- Patients for whom anesthesia was involved were significantly more likely to have a documented code status discussion (p=0.0057).
- Mortality was notably high in this population: overall 35% of the patients had died within 2-years; 3-month mortality was 23%.
- This study suggests that we need to improve our rate of documented code status discussions for patients who are not full code at the time of G-tube insertion.

## Limitations

- Results are observational and causality cannot be concluded.
- Sample size of patients who had code status other than full at time of G-tube is small, n = 33.
- Results are based on retrospective chart review of electronic medical record and thus conversations that were documented solely on paper were not accounted for.
- Results reflect only documented discussions. It is possible conversations occurred that were not documented.
